AB   The alpha2-macroglobulin receptor/low density lipoprotein receptor-related
     protein (LRP) is a large multifunctional receptor that interacts with a
     variety of molecules. It is implicated in biologically important
     processes such as lipoprotein metabolism, neurological function, tissue
     remodeling, protease complex clearance, and cell signal transduction.
     However, the regulation of LRP gene expression remains largely unknown.
     In this study, we have analyzed 2 kb of the 5'-flanking region of the LRP
     gene and identified a predicted peroxisome proliferator response element
     (PPRE) from -1185 to -1173. Peroxisome proliferator-activated receptor
     gamma (PPARgamma) ligands such as fatty acids and
     rosiglitazone increased functional cell surface LRP by 1.5-2.0-fold in
     primary human adipocytes and in the SW872 human liposarcoma cell line as
     assessed by activated alpha2-macroglobulin
     binding and degradation. These agents were found to increase LRP
     transcription. Gel shift analysis of the putative PPRE demonstrated
     direct binding of PPARgamma/retinoid X receptor alpha heterodimers to the
     PPRE in the LRP gene. Furthermore, these heterodimers could no longer
     interact with a mutated PPRE probe. The isolated promoter was functional
     in SW872 cells, and its activity was increased by 1.5-fold with the
     addition of rosiglitazone. Furthermore, the isolated response element was
     similarly responsive to rosiglitazone when placed upstream of an ideal
     promoter. Mutagenesis of the predicted PPRE abolished the ability of this
     construct to respond to rosiglitazone. These data demonstrate that
     fatty acids and rosiglitazone directly stimulate
     transcription of the LRP gene through activation of PPARgamma and increase
```

functional LRP expression.

AB Plasminogen activator inhibitor-1 (PAI-1) is a specific inhibitor of plasminogen activators and may be the principal regulator of plasminogen activation in vivo. PAI-1 levels are elevated in insulin-resistant subjects and are associated with an increased risk of atherothrombosis. After adjustment for metabolic parameters, increased PAI-1 levels were no longer considered as a cardiovascular risk factor. The mechanisms underlying the strong association between PAI-1 levels and the metabolic disturbances found in insulin resistance are still not understood. Several studies have suggested that visceral adipose tissue may be a major source of PAl-1. Accordingly, adipose tissue PAI-1 production particularly that from visceral fat, was found to be elevated in obese human subjects. Within human adipose tissue, stromal cells appear to be the main cells involved in PAI-1 synthesis. This review discusses the potential mechanisms linking adipose tissue to plasma PAI-1 levels such as the intervention of cytokines (TNFalpha and TGFbeta), free fatty acids and hormones (insulin and glucocorticoids). Moreover alteration of adipose tissue cellular composition induced by the modulation of PAI-1 expression opens a novel field of interest.

AB Myocardial infarction is the most common cause of congestive cardiac failure. Free radicals, cytokines, nitric oxide (NO) and antioxidants play a major role both in atherosclerosis and myocardial damage and preservation. In the early stages of atherosclerosis, neutrophils and monocytes infiltrate the intima and generate free radicals which damage the endothelial cells. As a result, production of NO and prostacyclin by the endothelial cells declines, which have cardioprotective actions. This also has relevance to the beneficial action of aspirin since, it can modulate both prostanoid and L-arginine-NO systems and NF-kB translocation. In both acute myocardial infarction and chronic congestive cardiac failure, the plasma levels of various inflammatory mediators such as interleukins and tumour necrosis factor-alpha (TNFalpha) are elevated. TNFalpha, produced by the inflammatory cells and the myocardium, can suppress myocardial contractility and induce the production of free radicals, which in turn can further damage the myocardium. Transforming growth factor beta (TGFbeta), polyunsaturated fatty acids and the glucose-insulin-potassium regimen can antagonize the harmful actions of TNFalpha and protect the myocardium. This explains why efforts made to reduce the levels of pro-inflammatory cytokines have beneficial action and preserve the myocardium.

LANGUAGE: English
AB The activity and plasma clearance of transforming growth factor (TGF)-β are known to be regulated by activated α2-macroglobulin (α2M*). This has been implicated in pathophysiol. processes, but no small mol. compds. have been reported to modulate TGF-β activity by affecting the interaction of TGF-β and α2M*. Here, we demonstrate that fatty acids are capable of inhibiting complex formation of TGF-β isoforms and α2M* as demonstrated by nondenaturing and SDS-PAGE. This is dependent on carbon chain length (C20, C18, C16, C14 > C12 > C10), degree of unsatn. (polyunsatd. > saturated), and TGF-β isoforms (TGF-β1 > TGF-β2 > TGF-β3). Arachidonic acid, which is one of the most potent inhibitors, is also capable of dissociating TGF-β-α2M* complexes, but higher concns. are required. Arachidonic acid appears to inhibit TGF-β-α2M* complex formation by binding specifically to α2M* as demonstrated by gel filtration chromatog. Arachidonic acid reverses the inhibitory effect of α2M* on TGF-β binding, TGF-β-induced growth inhibition, and TGF-β-induced transcriptional activation in mink lung epithelial cells and affects plasma clearance of TGF-β-α2M* complexes in mice. These results show that fatty acids are effective modulators of TGF-β activity and plasma clearance and may be useful in treating human diseases through their effects on the interaction of TGF-β and α2M*.
